Stipend

Vultr.com Ubuntu VPS Staking Wallet Set-Up guide

For staking to be effective, you need very high uptime. Serious stakers should consider using wallet on a VPS machine. This guide was created for less-experienced users. It's a one-click solution!

1. Register with Vultr.com

Go to <http://www.vultr.com>, create account and make small payment in Billing section - \$10 PayPal transfer will do just fine.

2. Create startup script

Navigate to Startup Scripts section on the main page.

Press "Add Startup Script" button. Type the script name, it can be anything you want. Leave script type as "Boot".

Now delete the example script, and replace it with content of this file:

<https://github.com/Stipend-Developer/stipend-vps-setup>

Press "Add Script". Make sure the rectangle changed color to blue.

3. Deploy new server

Press the big blue plus button on the right side of Vultr portal.

Now select preferred server location. Most nodes are located in USA, but it's yours to decide.

Server type: Ubuntu 16.04 x64

Server size: 20GB SSD - only \$2.50/mo. Wallet has been tested to work with 512MB ram, but you can choose \$5/mo version if you like. It's also possible to change plan later.

Startup script: select the script you created in Section 2.

Press "Deploy Now"

4. Log in to your VPS desktop

Your VPS is being configured now. You can open the console and check progress. The View Console is found in your server details menu.

After few minutes script will finish and console will greet you with login window. Select "Other" from the pull down menu.

Now login typing "root" as your username and your retype your password found at Server Information page.

After first login, the password window won't show again and you will boot straight to desktop.

Now just run the stipend-gui.

Congratulations! You have your fully working Stipend wallet running in VPS.

4. Troubleshooting - known issues

I followed your guide, but nothing is happening

This is the most common problem. Make sure you selected the install script while adding new VPS instance. The field with script name must change color to blue.

Login screen won't accept my password

Vultr web console has problems with keyboard layouts other than generic US. Use Putty (or other SSH terminal) to connect to your VPS, login then use passwd command to change password.

Make sure it contains only letters and numbers, no special characters. Now you should be able to login.
